

# The ATLAS detector: status and plans

THE 4th INTERNATIONAL SAKHAROV  
CONFERENCE ON PHYSICS  
MOSCOW, May 18--23, 2009

1981 International Symposium on Lepton  
and Photon Interactions at High Energies

Bonn, August 24-29, 1981

PARTICLE PHYSICS PROSPECTS: AUGUST ' 81

I. B. OKUN

At present the scalarland exists only in the dreams of theoreticians, who describe it in many ways, which are quite far from being selfconsistent. The aim of this talk is to urge experimentalists and accelerator builders to join their efforts in discovering this land, which lies below and not far above 1 TeV.

During the last 50 years physicists solve problems by inventing hypothetical particles, which eventually become real. It took 14 years to discover the first hypothetical spinless particle: the pion. It is now precisely 14 years that we live with a new type of hypothetical spinless bosons. Isn't it about time to discover them?

## LARGE HADRON COLLIDER IN THE LEP TUNNEL

A feasibility study of possible options

by

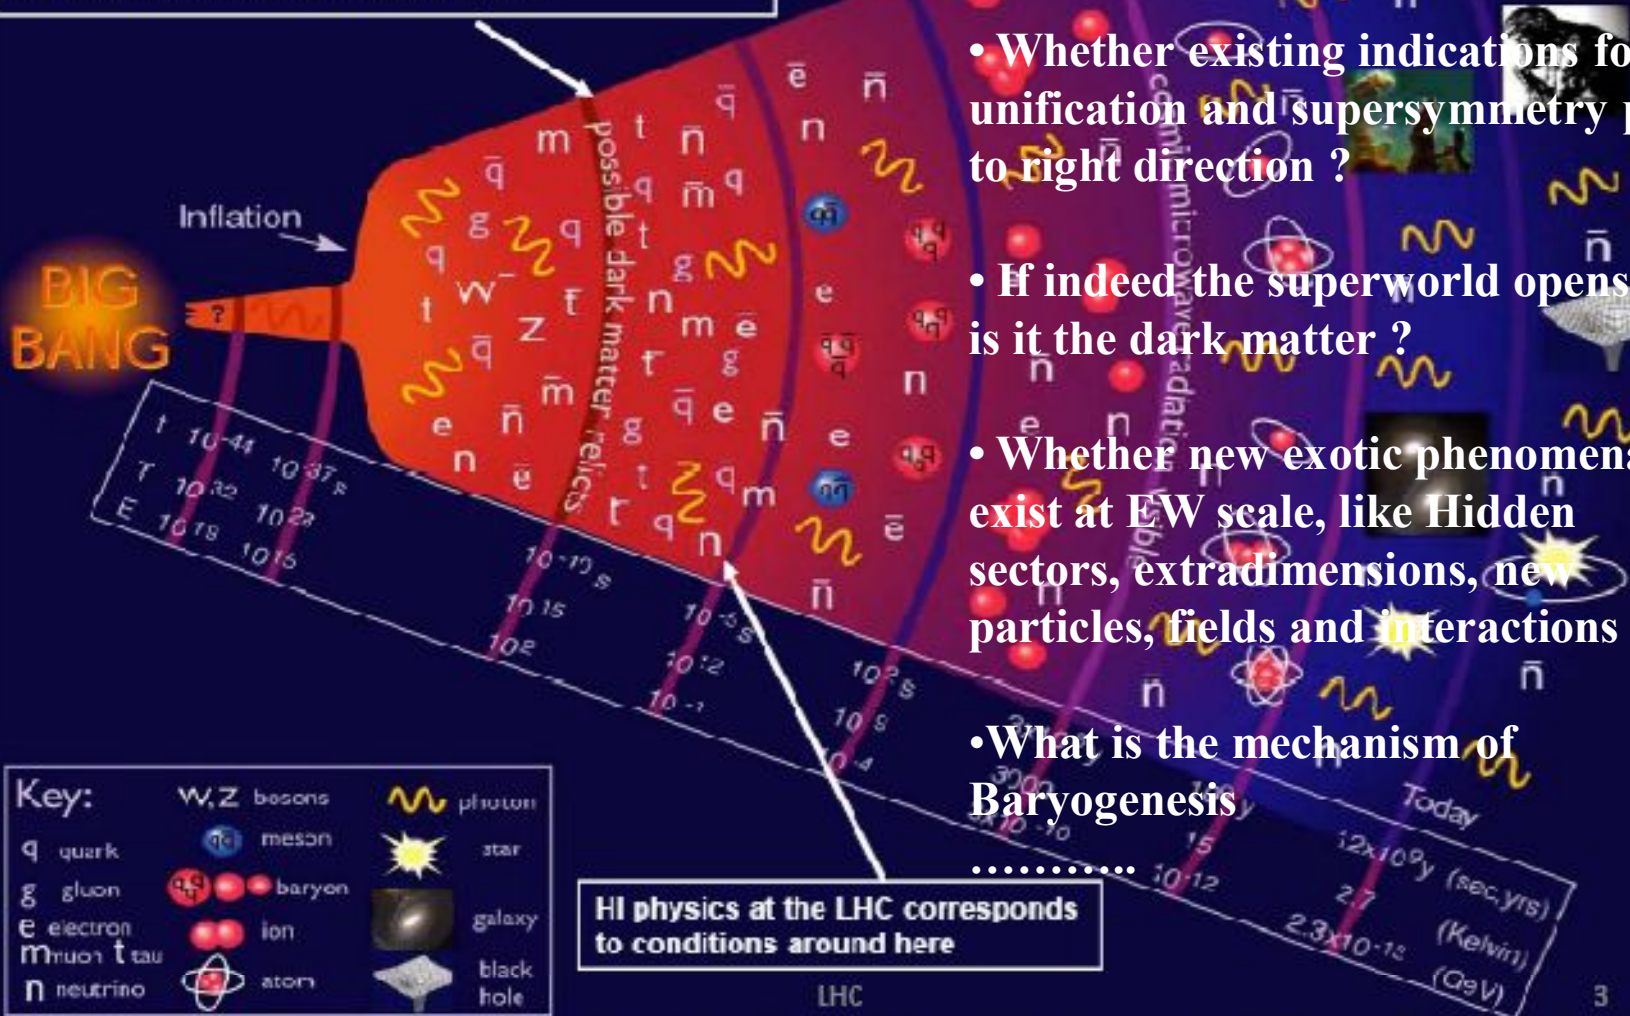

The CERN Machine Group

- 1984 : first studies
  - 1990 : Aachen workshop
  - Summer 1992 : Evian workshop
  - End 1992:  
ATLAS Letter Of Intent
  - No very significant  
change of detector design since
  - 1994 The CERN Council approves the  
construction of the LHC
  - 1998 The first prototype magnet with a 15  
metre nominal length is tested
  - 2008 First beam
  - 2009 First collision
  - 2010 First result
  - 2014 Upgrade 1
  - 2019 Upgrade 2
  - .....
- ≈ half of century project**

# History of the Universe

pp physics at the LHC corresponds to conditions around here

• What breaks EW symmetry (origin of mass)?

• Whether existing indications for unification and supersymmetry point to right direction?

• If indeed the superworld opens up, is it the dark matter?

• Whether new exotic phenomena exist at EW scale, like Hidden sectors, extradimensions, new particles, fields and interactions?

• What is the mechanism of Baryogenesis

HI physics at the LHC corresponds to conditions around here

CERN Courier, 1993

*On 28 June, several days after the meeting of CERN's governing Council, Russian Science Minister Boris Saltykov (left) and CERN Director General Carlo Rubbia signed an updated cooperation agreement between Russia and CERN.*

- pp  $\sqrt{s} = 10\text{-}14$  TeV  $L_{\text{design}} = 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$  (after 2012/3)
- Heavy ions  $L_{\text{initial}} < \text{few} \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$  (before)
- Note:  $\sqrt{s}$  is x7 Tevatron,  $L_{\text{design}}$  is x100 Tevatron (e.g. Pb-Pb at  $\sqrt{s} \sim 1000$  TeV)

First collisions:  
expected in  
November 2009

ATLAS and CMS :  
pp, general purpose

LHC 27 km ring (previously  
used for the LEP  $e^+e^-$  collider)

Plus two much smaller  
experiments with very  
forward detectors at  
Point-1: LHCf  
Point-5: Totem

ALICE :  
ion-ion,  
p-ion

LHCb :  
pp, B-physics, CP-violation

# Main parameters of the machine

	Design operation		
Beam energy	7	TeV	
Dipole field	8.4	T	
Dipole current	11700	A	
Instantaneous luminosity L	$10^{34}$	$\text{cm}^{-2}\text{s}^{-1}$	
Integrated luminosity/year	$\sim 100$	$\text{fb}^{-1}$	
Circulating current/beam	0.53	A	
Number of bunches	2808+2808		← Tevatron: 36+36
Bunch spacing	25	ns	← Tevatron: 396 ns
Protons per bunch	$10^{11}$		
R.m.s. beam radius at IP1/5	16	$\mu\text{m}$	
R.m.s. bunch length	7.5	cm	
Stored beam energy	360	MJ	← x200 Tevatron
Crossing angle	300	$\mu\text{rad}$	
Number of events per crossing	$\sim 20$		
Luminosity lifetime	10	hours	

ATLAS superimposed to the 5 floors of building 40

# Strategy to prepare the ATLAS detectors for physics

- Strict quality controls during detector construction in order to meet performance requirements
- 15 year long test beam campaign in order to understand (and calibrate large parts of the detectors) and validate/tune software tools
- Detailed simulation of realistic detector including misalignments, material non-uniformities, etc. in order to test and validate calibration/alignment strategies
- Commissioning of completed detectors in the underground caverns using cosmic rays and “LHC beams”
- Commissioning and calibration with physics
- Understanding SM backgrounds to New Physics
- **Discovery of New Physics ...**

# Commissioning with cosmics in the underground cavern

**Started more than three years ago. Very useful to:**

- Run an increasingly more complete detector with final trigger, data acquisition and monitoring systems. Data analyzed with final software
- Shake-down and debug the experiment in its final position → fix problems
- Perform first calibration and alignment studies

# Inner Detector

**The Inner Detector (ID) is organized into three sub-systems:**

**Pixels**

**( $0.8 \cdot 10^8$  channels)**

**Silicon Tracker (SCT)**

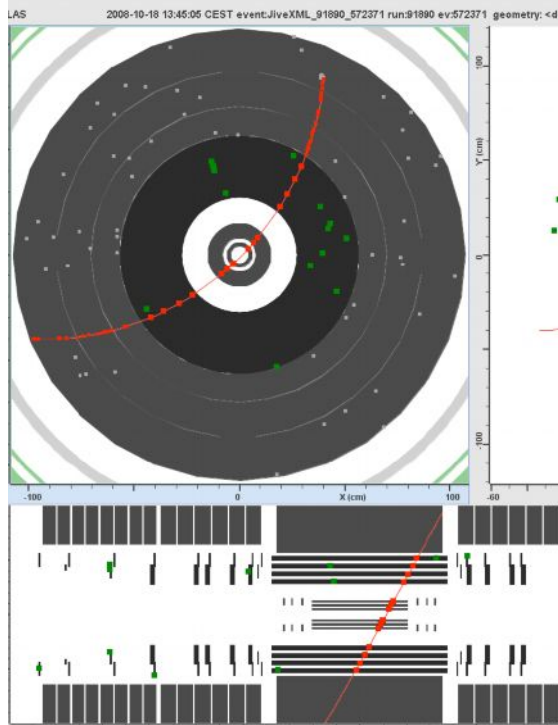

**( $6 \cdot 10^6$  channels)**

**Transition Radiation Tracker (TRT)**

**( $4 \cdot 10^5$  channels)**

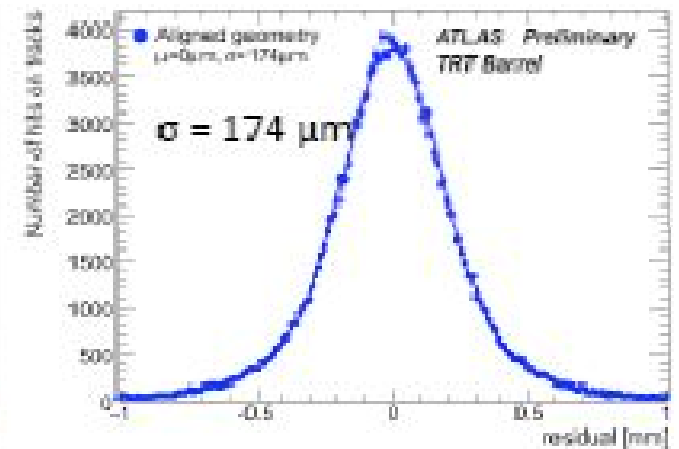

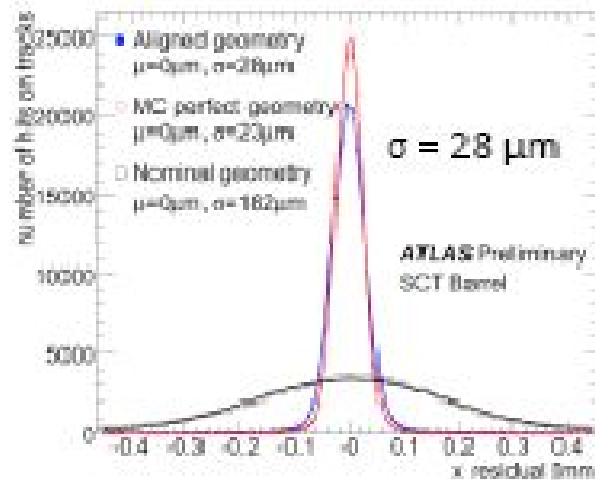

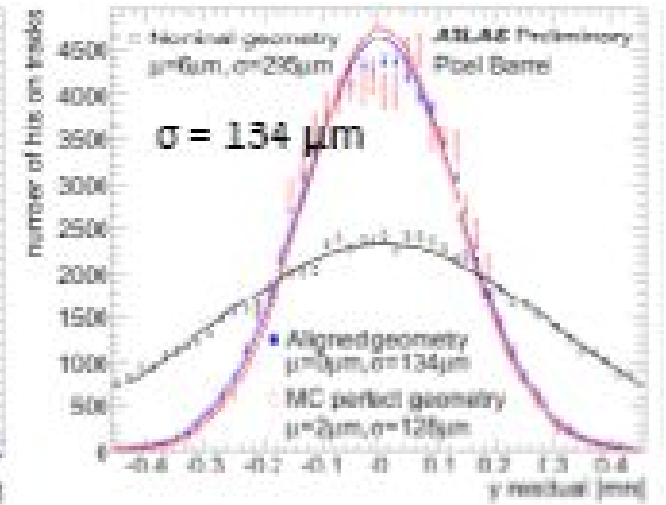

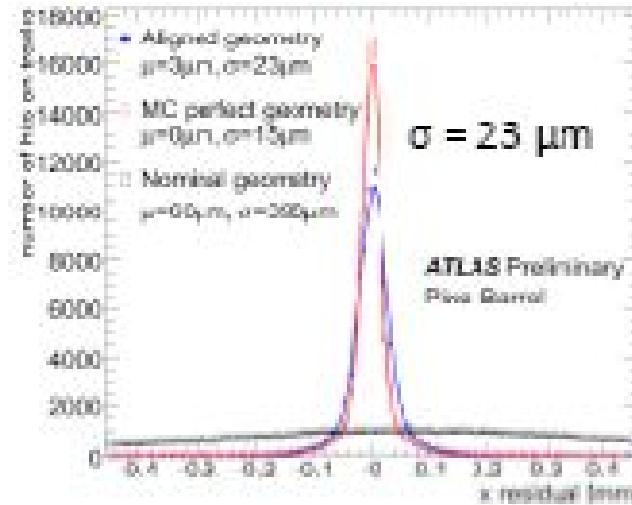

# Inner Detector - Alignment with tracks

Track residuals close to perfect geometry

(residual – distance between the fitted track and the hit in the layer)

# Inner Detector - Results

Bubble chamber like picture in barrel TRT (cosmic shower)

Probability of high amplitudes (due to transition radiation).  
Good agreement with test beam data.

# Calorimetry

Electromagnetic energy resolution:

$$\sigma(E)/E = 10\%/\sqrt{E} \oplus 0.7\%$$

Hadronic energy resolution:

$$\sigma(E)/E = 50\%/\sqrt{E} \oplus 3\% \quad (\eta < 3.2)$$

$$\sigma(E)/E = 100\%/\sqrt{E} \oplus 10\% \quad (\eta > 3.1)$$

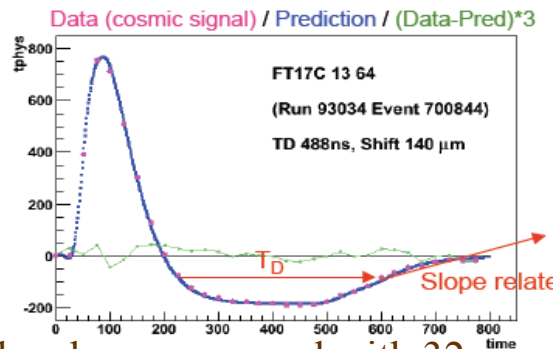

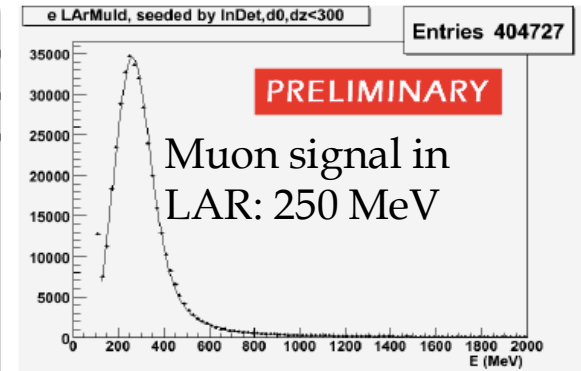

## Liquid Argon Calorimeter

- Electromagnetic (barrel+endcap)  
Pb-LAr accordion geometry
- Endcap hadronic Cu-LAr
- Forward hadronic Cu/W-LAr
- Electronic calibration

## Tile Calorimeter (barrel hadronic)

- Iron scintillator tiles (3 longitudinal samples)
- Calibration system (Cs source, Laser, charge injecton)

# Calorimetry - Status

Pulse shape measured with 32 samples

- Very small # of non-working channels.
- During 2008 run one HEC power supply not working.
- Very stable pedestals
- Enough data was taken to check parameterization.
- Timing is already set to within a few ns.

Muon energy Loss in Tilecal

- Dead channels: < 1.4% to be repaired during shutdown
- Timing has been set for all modules at the level of a few ns.
- Energy response for cosmic MUONs is uniform across the full calorimeter.
- Good position matching is being achieved between Tile-LAr and ID tracks.

# MUON Spectrometer

- System composed of:
  - Magnets
  - Tracking chambers (MDT and CSC)
  - Alignment system (Barrel and End-Cap)
  - Trigger Chambers (RPC and TGC)

# Magnet system

**Solenoid** (1 coil) 2 T field

**Barrel Toroid** (8 coils)

0.2-2.5 T field

**Two end-cap toroids**

(2 x 8 coils) 0.2-3.5 T

## Status

Stable continuous operation at nominal field.

Stress and heat distributions during fast quench are safe.

Geometrical distortions of Barrel toroid with field on as expected.

## Magnetic Field knowledge:

Magnetic field was measured with probes on chambers to determine where the coils are located to within 1 mm.

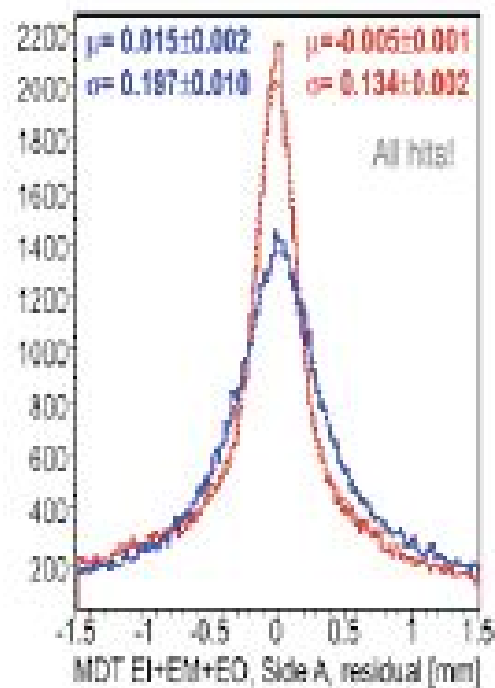

## Muon tracking chambers

MDT eff.:

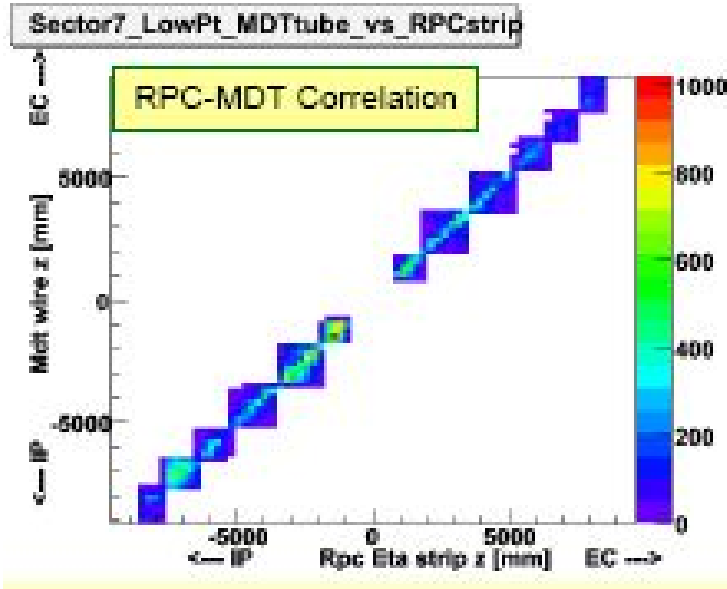

Find segment in 3rd  
Station using other 2  
99%

CSC started operation with  
initial resolutions at the  
mm level

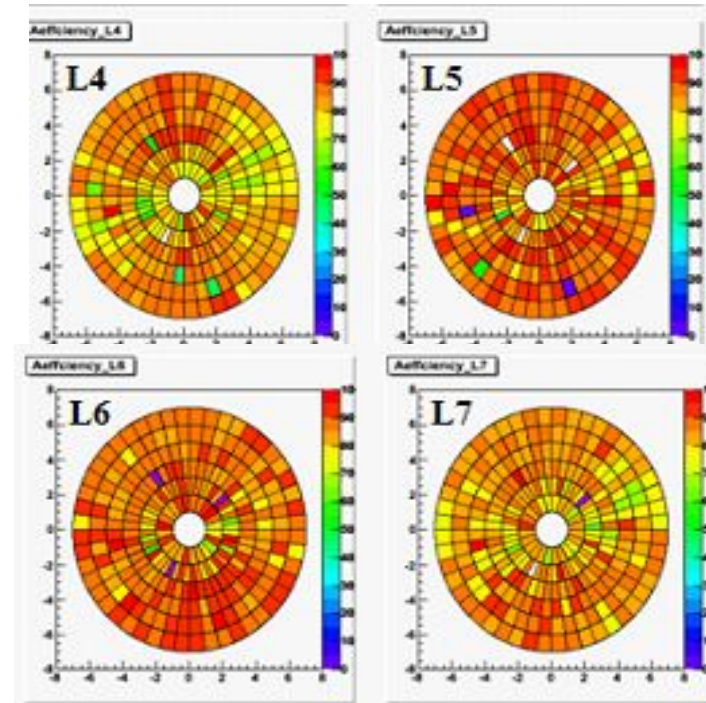

Track residuals in barrel and End-Cap  
(red after alignment corrections)  
Sigma~135microns, goal 80 microns

# Trigger Chambers

More than 50% of the RPC towers have been timed-in. Efficiency of individual layers and of coincidence is reaching its expected level. Good matching between tracking and trigger chambers for finding the tracks.

All TGC detectors have been timed-in for collisions. The efficiency for each individual plane is as expected for cosmics (not well defined time of arrival). Although without final TGC alignment, matching with MDT tracks is good

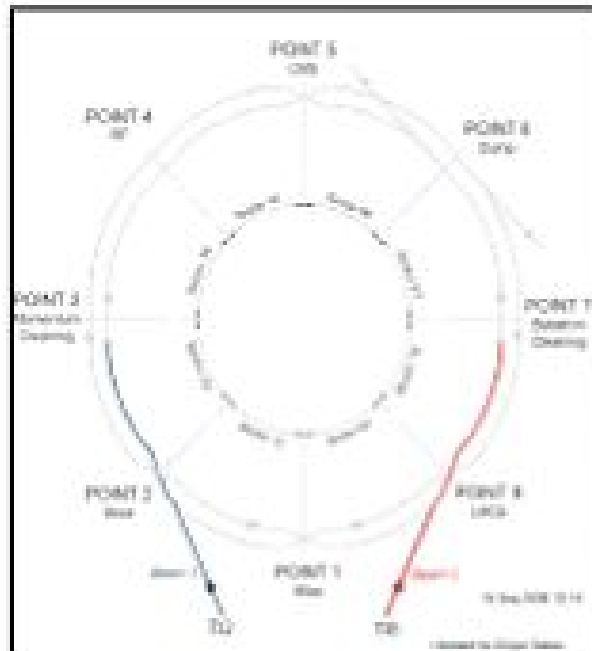

16 June 2008: Last piece of LHC ring being put in place

# First Turn! 10 Sept 2008

**10:30 am**  
**Two beam spots on a screen near ALICE indicate that Beam 1 has made 1 turn**

**10:30 : Beam 1 (clockwise) around the ring (in ~ 1 hour), makes ~ 3 turns, then dumped**

**15:00 : Beam 2 (counter-clockwise) around the ring, makes 3-4 turns, then dumped**

**22:00 : Beam 2 circulates for hundreds of turns ...**

**Beam Energy: 450 GeV, Beam Intensity:  $2 \times 10^9$  protons per bunch**

# Beam splash events have been successfully recorded by ATLAS

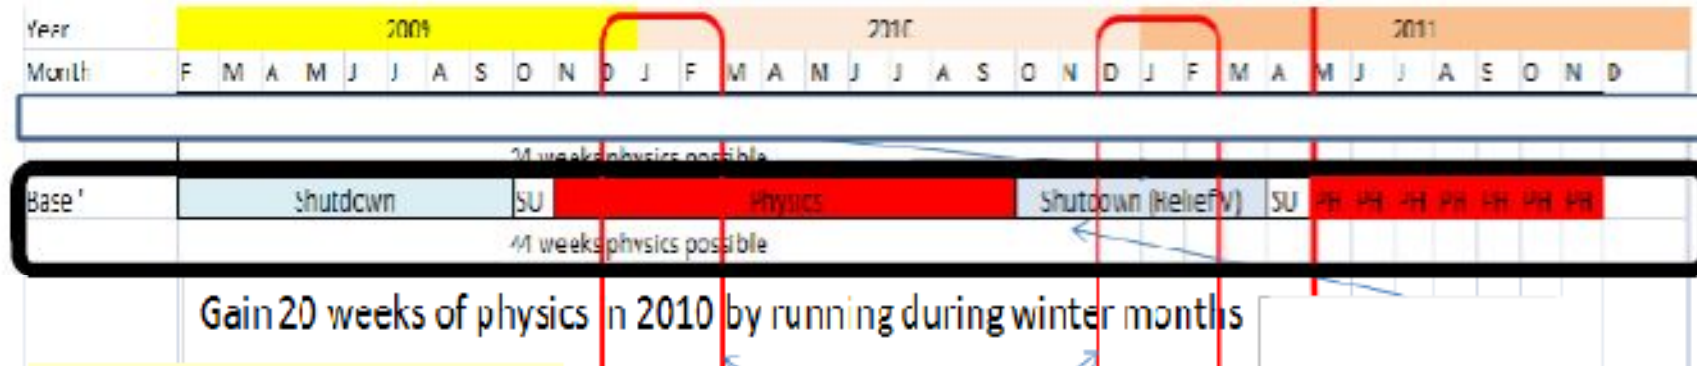

### **LHC Incident on 19 Sept. 2008**

- Most likely, an electrical arc developed, which punctured the He enclosure
- Large amounts of He gas were released into the insulating vacuum of the cryostat

### **LHC repair and restart**

- Broken magnets will be replaced or repaired
- Sectors will be equipped with extra pressure relief valves
- The quench protection system will be upgraded everywhere

## Summary of the New LHC Schedule

The plan is:

- Machine ready for start-up operation again in October 2009
- Run the LHC over winter until September 2010
- This first physics run will be at 10 TeV collision energy
- The end of the run, end of summer 2010
- Estimated integrated luminosity: from  $\approx 100\text{pb}^{-1}$  to  $\approx 500\text{pb}^{-1}$
- There will be also a first run with heavy ion collisions

What do we expect if centre-of-mass energy is reduced?

Larger decrease in cross section for high mass particles also due to less gluon and sea quarks at high  $x$

Mass scale =  $\sqrt{s} * \sqrt{x_1} * \sqrt{x_2}$

# First physics data

~100 pb-1 per experiment may be collected within a month

<b>Channels (examples ...)</b>	<b>Events to tape for 100 pb-1 (ATLAS)</b>	<b>Total statistics from</b>	
		<b>LEP</b>	<b>and Tevatron</b>
$W \rightarrow \mu \nu$	$\sim 10^6$	$\sim 10^4$	$\sim 10^{6-7}$
$Z \rightarrow \mu \mu$	$\sim 10^5$	$\sim 10^6$	$\sim 10^{5-6}$
$t\bar{t} \rightarrow W b \ W \bar{b} \rightarrow \mu \nu + X$	$\sim 10^4$		$\sim 10^{3-4}$
QCD jets $p_T > 1 \text{ TeV}$	$> 10^3$		---
$\tilde{g}\tilde{g} \quad m = 1 \text{ TeV}$	$\sim 50$		---

# Calibration W, Z and J/Psi

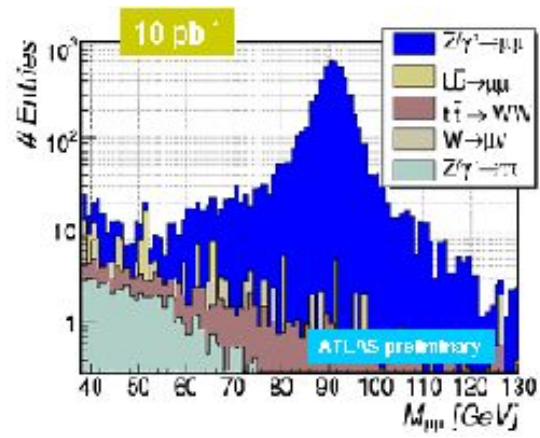

1 pb<sup>-1</sup> ≡ 3 days at 10<sup>31</sup> at 30% efficiency

Full sim. study scaled using ATLFast and simple acceptance cuts

Yield with fiducial acceptance cuts: muon with p<sub>T</sub>>6 GeV, and second with p<sub>T</sub>>4 GeV, all with |eta|<2.5

Similar number of W and Z events as the Tevatron 2010 at v<sub>s</sub>=10 TeV with O(1) fb<sup>-1</sup>

Already with about O(50) pb<sup>-1</sup> at 10 TeV enough W, Z and J/psi events for a quite good detector calibration  
 Electron scale < 1% in 0.2x0.4 eta-phi bins,  
 Muon momentum scale and alignment known at the 1% level

# The first top quarks in Europe

A top signal can be observed quickly, even with limited detector performance and simple analysis .... and then used to calibrate the detector and understand physics

$$\sigma_{tt} \approx 250 \text{ pb for } tt \rightarrow bW \text{ } bW \rightarrow bl\nu \text{ } bjj$$

ATLAS preliminary

3 jets  $p_T > 40 \text{ GeV}$   
1 jets  $p_T > 20 \text{ GeV}$

Isolated lepton  
 $p_T > 20 \text{ GeV}$

$E_{T \text{ miss}} > 20 \text{ GeV}$

3 jets with largest  $\sum p_T$

Top signal observable in early days with no b-tagging and simple analysis ( $\sim 3000$  evts for  $100 \text{ pb}^{-1}$ )  $\rightarrow$  measure  $\sigma_{tt}$  to  $\sim 20\%$ ,  $m_t$  to  $< 10 \text{ GeV}$  with  $100 \text{ pb}^{-1}$ ? (ultimate LHC precision on  $m_t$ :  $\sim 1 \text{ GeV}$ )

In addition, excellent sample to:

- commission b-tagging, set jet E-scale using  $W \rightarrow jj$  peak, ...
- understand / constrain theory and MC generators using e.g.  $p_T$  spectra

# Standard Model Higgs

$H \rightarrow WW \rightarrow \ell\nu\ell\nu$  only

Compare sensitivity to Tevatron with  $8 \text{ fb}^{-1}$

To match Tevatron with  $E_{\text{cm}}$  of 10 TeV, need 100-200  $\text{pb}^{-1}$

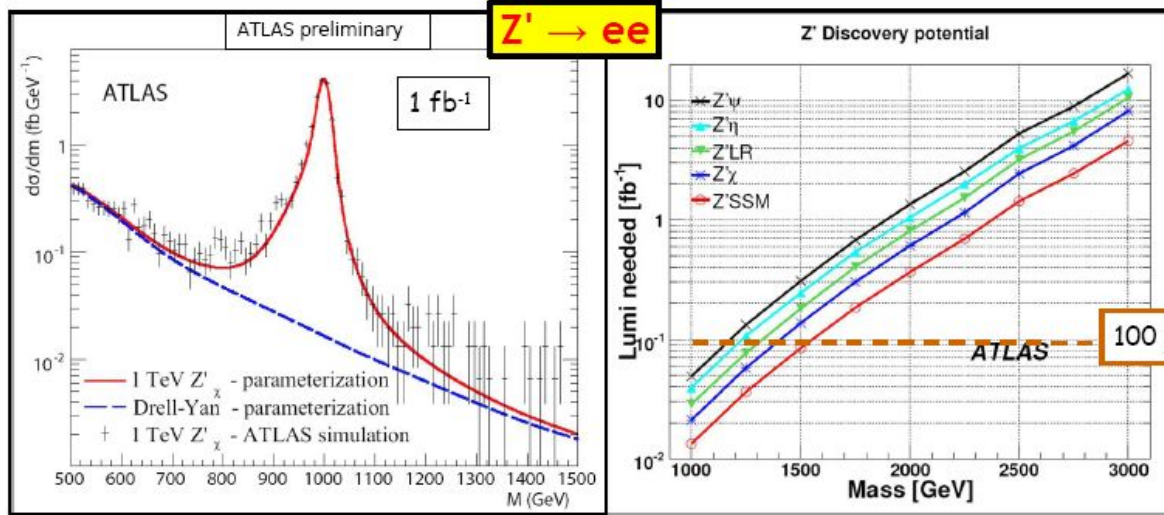

Massive loss of sensitivity below 6 TeV

Combination of 0j and 2j, H to WW to ll

With  $1 \text{ fb}^{-1}$ ,  $5\sigma$  discovery reach opens, provided  $E_{\text{cm}}$  above 8 TeV

# Z' and W' – candidates for new physics

- Z' mass peak on top of small Drell-Yan background
- with 100 pb<sup>-1</sup> large enough signal for discovery up to  $m \sim 1.5$  TeV in sequential SM
- current Tevatron 95% CL limit  $\sim 1$  TeV

$$\sigma(10 \text{ TeV}) \sim \frac{1}{2} \sigma(14 \text{ TeV})$$

# Supersymmetry

## l+jets+missing- $E_T$ channel

- Not most sensitive, but will be usable before inclusive jets+missing- $E_T$  analysis

Tevatron limit currently is 380 GeV in this model ( $m_{\tilde{q}} = m_{\tilde{g}}$ )

5 $\sigma$  discovery beyond current Tevatron limits possible with  $\sim 20 \text{ pb}^{-1}$  at 10 TeV

## With time and data, the LHC can also discover:

Excited quarks $q^* \rightarrow \gamma q$ :	up to $m \approx 6$ TeV
Leptoquarks:	up to $m \approx 1.5$ TeV
Monopoles $pp \rightarrow \gamma(pp)$ :	up to $m \approx 20$ TeV
Compositeness:	up to $\Lambda \approx 40$ TeV
$Z' \rightarrow ll, jj$ :	up to $m \approx 5$ TeV
$W' \rightarrow l\nu$ :	up to $m \approx 6$ TeV
etc.... etc....	

Large number of scenarios studied

Main conclusions:

- ⇒ LHC direct discovery reach up to  $m \sim 5-6$  TeV
- ⇒ demonstrated detectors sensitivity to many signatures
- robustness, ability to cope with unexpected scenarios

8% of the ATLAS detector made in Russia
